CONTENT:
Section 1. Fractures and luxations of permanent teeth
Section 2. Avulsion of permanent teeth
Section 3. Traumatic injuries to primary teeth

Disclaimer: These guidelines are intended to provide information for health care providers caring for patients with dental injuries. They represent the current best evidence based on literature research and professional opinion. As is true for all guidelines, the health care provider must apply clinical judgment dictated by the conditions present in the given traumatic situation. The IADT does not guarantee favorable outcomes from following the Guidelines, but using the recommended procedures can maximize the chances of success.

These Guidelines have been endorsed by the following professional organizations: The American Association of Endodontists
INTRODUCTION

Traumatic dental injuries (TDIs) occur with great frequency in preschool, school age children and young adults comprising 5% of all injuries for which people seek treatment. A twelve year review of the literature reports that 25% of all school children experience dental trauma and 33% of adults have experienced trauma to the permanent dentition with the majority of injuries occurring before age 19. Luxation injuries are the most common TDIs in the primary dentition, whereas crown fractures are more commonly reported for the permanent dentition. TDIs present a challenge to clinicians worldwide. Consequently, proper diagnosis treatment planning and followup are critical to assure a favorable outcome.

Guidelines, among other things, should assist dentists, other health care professionals and patients in decision making. Also, they should be credible, readily understandable and practical with the aim of delivering appropriate care as effectively and efficiently as possible.

The following guidelines by the International Association of Dental Traumatology (IADT) represent an updated set of guidelines based on the original guidelines published in 2007. The update was accomplished by doing a review of the current dental literature using EMBASE, MEDLINE, and PUBMED searches from 1996-2011 as well as a search of the journal of Dental Traumatology from 2000 to 2011. Search words included tooth fractures, root fractures, tooth luxation, lateral luxation and permanent teeth, intruded permanent teeth, and luxated permanent teeth.

The primary goal of these guidelines is to delineate an approach for the immediate or urgent care of TDIs. It is understood that subsequent treatment may require secondary and tertiary interventions involving specialist consultations, services and/or materials/methods not always available to the primary treating clinician.

The IADT published its first set of guidelines in 2001 and updated them in 2007. As with the previous guidelines, the working group included experienced investigators and clinicians from various dental specialties and general practice. This revision represents the best evidence based on the available literature and expert professional judgment. In cases where the data did not appear conclusive, recommendations are based on the consensus opinion of the working group followed by review by the members of the IADT Board of Directors. It is understood that guidelines are to be applied with evaluation of the specific clinical circumstances, clinicians’ judgement and patients’ characteristics, including but not limited to compliance, finances and understanding of the immediate and long-term outcomes of treatment alternatives versus non-treatment. The IADT cannot and does not guarantee favorable outcomes from strict adherence to the Guidelines, but believe that their application can maximize the chances of a favorable outcome.

Guidelines undergo periodic updates. These 2012 Guidelines will appear in three parts:

**Part I: Fractures and luxations of permanent teeth**

**Part II: Avulsion of permanent teeth**

**Part III: Injuries in the primary dentition**

Guidelines offer recommendations for diagnosis and treatment of specific TDIs; however, they do not provide the comprehensive nor detailed information found in textbooks, the scientific literature and most recently the Dental Trauma Guide (DTG) which can be accessed on [http://www.dentaltraumaguide.org](http://www.dentaltraumaguide.org). Additionally, the DTG, also available on the IADT’s web page [http://www.iadt-dentaltrauma.org](http://www.iadt-dentaltrauma.org) provides a visual and animated documentation of treatment procedures as well as estimations of prognosis for the various TDIs.

GENERAL RECOMMENDATIONS

Clinical Examination
Detailed description of protocols, methods and documentation for clinical assessment of TDIs can be found in current textbooks.1,14,15

Radiographic Examination

Several projections and angulations are routinely recommended but the clinician should decide which radiographs are required for the individual. The following are suggested:

- Periapical radiograph with a 90° horizontal angle with central beam through the tooth in question.
- Occlusal view.
- Periapical radiograph with lateral angulations from the mesial or distal aspect of the tooth in question.

Emerging imaging modalities such as cone beam computerized tomography (CBCT) provide enhanced visualization of TDIs, particularly root fractures and lateral luxations, monitoring of healing and complications. Availability is limited and its use not currently considered routine, however, specific information is available in the scientific literature.16,17

Splinting: Type and Duration

Current evidence supports short-term, non-rigid splints for splinting of luxated, avulsed and root-fractured teeth. While neither the specific type of splint nor the duration of splinting are significantly related to healing outcomes (except for avulsion where the time may be of importance), it is considered best practice in order to maintain the repositioned tooth in correct position, provide patient comfort and improved function.18-23

Use of Antibiotics

There is limited evidence for use of systemic antibiotics in the management of luxation injuries and no evidence that antibiotic coverage improves outcomes for root fractured teeth. Antibiotic use remains at the discretion of the clinician as TDI’s are often accompanied by soft tissue and other associated injuries, which may require other surgical intervention. In addition, the patient’s medical status may warrant antibiotic coverage.23,24

Sensibility Tests

Sensibility testing refers to tests (cold test and/or electric pulp test) attempting to determine the condition of the pulp. At the time of injury sensibility tests frequently give no response indicating a transient lack of pulpal response. Therefore, at least two signs and symptoms are necessary to make the diagnosis of necrotic pulp. Regular followup controls are required to make a pulpal diagnosis.
Immature versus Mature Permanent Teeth

Every effort should be made to preserve pulpal vitality in the immature permanent tooth in order to ensure continuous root development. The vast majority of TDIs occur in children and teenagers where loss of a tooth has lifetime consequences. The immature permanent tooth has considerable capacity for healing after traumatic pulp exposure, luxation injury and root fractures. Pulp exposures secondary to TDIs are amenable to proven conservative pulp therapies that maintain vital pulp tissue and allow for continued root development. In addition, emerging therapies have demonstrated the ability to revascularize/regenerate vital tissue in canals of immature permanent teeth with necrotic pulps. Teeth frequently sustain a combination of several injuries. Studies have demonstrated that crown fractured teeth with or without pulp exposure and associated luxation injury experience a greater frequency of pulp necrosis. The mature permanent tooth that sustains a severe TDI after which pulp necrosis is anticipated is amenable to preventive pulpectomy as root development is substantially completed.

Pulp Canal Obliteration

Pulp canal obliteration (PCO) occurs more frequently in teeth with open apices which have suffered a severe luxation injury. It usually indicates ongoing pulpal vitality. Extrusion, intrusion and lateral luxation injuries have high rates of PCO. Subluxated and crown fractured teeth also may exhibit PCO although with less frequency. Additionally PCO is a common occurrence following root fractures.

Patient Instructions

Patient compliance with follow-up visits and home care contributes to better healing following a TDI. Both patients and parents of young patients should be advised regarding care of the injured tooth/teeth for optimal healing, prevention of further injury by avoidance of participation in contact sports, meticulous oral hygiene and rinsing with an antibacterial such as chlorhexidine gluconate 0.1% alcohol free for 1-2 weeks.

Additional Resources

Besides the general recommendations above, clinicians are encouraged to access the DTG, the journal Dental Traumatology, and other journals for information pertaining to treatment delay, intrusive luxations, root fractures, pulpal management of fractured and luxated teeth, splinting, and antibiotics.
